Abstract

The main parameters of the plough body that determine the ploughing efficiency are the initial and the final soil strip lifting angles on the share-mouldboard surface, the angles of its horizontal generatrix, the radius of this surface and the working width of the body. By using analytical correlations derived as a result of theoretical research, a computer algorithm has been worked out for simulating the functions of the plough body and the forces exerted by soil upon the operating parts, as well as its draft resistance depending on the share inclination angle, determining the initial lifting angle. By increasing it the draft resistance increases. For economical ploughing its optimum varies between 28°...32°.

Key words: plough body parameters, forces acting on the plough body, draft resistance, analytic correlations, optimisation of parameters, share inclination angle.

Introduction

Ploughing is one of the most power-consuming and expensive processes in agricultural production. It is known from our previous investigation /Vilde, 1999, 2004; Rucins, Vilde, 2005/ that the draft resistance of ploughs and energy requirement for ploughing depend on the plough body parameters and on such soil properties as its hardness, density, friction and adhesion. However, there were no sufficient analytical correlations that would enable to determine the impact of the share inclination angle on the draft resistance of the share-mouldboard surface and the plough body, as a whole, as well as on the ploughing quality and expenses depending on the body parameters.

The purpose of the investigations is to study the factors that determine the quality and energy requirement of ploughing, the impact of body parameters on it and to find technical solutions for its improvement.

Materials and Methods

The objects of the research are the forces acting on the plough body and its draft resistance depending on the body design parameters, as well as the physical and mechanical properties of soil and the mode of operation. On the basis of the previous investigations /Vilde, 1999/ a computer algorithm has been worked out /Rucins, Vilde, 2005/ for the simulation of the forces exerted by soil upon the operating (lifting and

supporting) surfaces of the plough body, and the draft resistance caused by these forces (Fig. 1).

Figure 1. Scheme of the plough body, its parameters and acting forces.

Results and Discussion

Mathematical methods and computer algorithms worked out for the simulation of soil tillage processes allow calculating the forces acting upon the machine operating parts and their optimal design (including the plough body) for qualitative soil tillage with minimum energy consumption [Vilde, 1999, 2004; Rucins, Vilde, 2004, 2005]. According to this investigation the draft resistance R_x of the plough body is determined by the share cutting resistance R_{Px} , the resistance caused by weight R_{Gx} of the strip lifted, by the inertia forces R_{Jx} , by soil adhesion R_{Ax} and by weight R_{Qx} of the plough body itself (including a part of the weight of the plough). However, the latter is not dependent on the plough parameters.

$$R_x = \sum R_{ix} = R_{Px} + R_{Gx} + R_{Jx} + R_{Ax} + R_{Qx} \quad (1)$$

The vertical reaction R_z and the lateral reaction R_y of the operating part are defined by the sum of corresponding partial reactions:

$$R_z = \sum R_{iz} \quad R_y = \sum R_{iy} \quad (2; 3)$$

The total draft resistance R_x of the operating part is composed of the resistance of the working surface R'_x and the resistance of the supporting (lower and lateral) surfaces R''_x :

$$R_x = R'_x + R''_x = \sum R'_{ix} + f_0 \left(\sum R_{iz} + \sum R_{iy} + p_{Axy} S_{xy} + p_{Axz} S_{xz} \right), \quad (4)$$

where f_0 is the coefficient of soil friction along the working and supporting surfaces of the operating part; p_{Axy} and p_{Axz} – specific adhesion force, respectively, to the lower and the lateral supporting surfaces of the operating part; S_{xy} and S_{xz} – the surface area of the lower and the lateral supporting surfaces of the operating part.

Cutting resistance R'_{Px} is proportional to soil hardness ρ_0 and the share edge surface area ω :

$$R'_{Px} = k_p \rho_0 i b \quad (5)$$

where k_p is the coefficient involving the impact of the shape of the frontal surface of the ploughshare edge; i and b – the thickness and width of the edge.

It is evident from formula (5) that the friction of soil along the edge does not influence the cutting resistance of the edge.

At a sharp ploughshare (the rear bevel is absent):

$$R_{Pz} = 0 \quad (6)$$

At a blunt (threadbare) ploughshare having rear bevel the vertical reaction RPz on the hard soils can reach the summary value of vertical reactions, this summary value arising from other forces acting on the share-mouldboard surface (soil gravity and inertia) and the weight of the body Q .

At an inclined ploughshare a lateral reaction RPy arises, its value being affected by the friction reaction.

$$R_{Py} = k_p \rho_0 i b c t g(\gamma_0 + \varphi_0) \quad (7)$$

where γ_0 is the inclination angle of the edge towards the direction of movement (the wall of the furrow); φ_0 - the angle of friction.

Friction of soil along the ploughshare edge reduces the lateral pressure of the ploughshare (the pressure of the plough body against the wall of the furrow).

The resistance of the supporting surface

$$R''_{Px} = k_p \rho_0 i b f_0 c t g(\gamma_0 + \varphi_0) = F''_{Px} \quad (8)$$

The total cutting resistance

$$R_{px} = k_p \rho_0 i b [1 + f_0 \operatorname{ctg}(\gamma + \varphi_0)] \quad (9)$$

The lateral cutting resistance of the knife is determined by formulae, similar to those for the cutting resistance from below. Consequently, similar to the above formulae will also be the formulae defining the impact of friction on the total resistance of the knife.

Forces caused by the weight of the lifting soil strip:

$$R'_{Gx} \approx q \delta g k_y r \sin^{-1} \gamma \left\{ [(\sin \gamma \cos \varepsilon_1 + \cos^2 \gamma \sin^{-1} \gamma) e^{f_0 \sin \gamma (\varepsilon_1 - \varepsilon_2)} - (\sin \gamma \cos \varepsilon_2 + \cos^2 \gamma \sin^{-1} \gamma)] \cos \varepsilon_1 (\cos \varepsilon_1 e^{f_0 \sin \gamma (\varepsilon_2 - \varepsilon_1)} - \cos \varepsilon_2) \right. \\ \left. * (\cos \varepsilon_1 - f_0 \sin \varepsilon_1 \sin \gamma)^{-1} \sin \varepsilon_1 [\sin \varepsilon_1 \sin \gamma + f_0 (\sin^2 \gamma \cos \varepsilon_1 + \cos^2 \gamma)] \right\} \quad (10)$$

$$R_{Gz} \approx q \delta g r \sin^{-1} \gamma (\varepsilon_2 - \varepsilon_1) \quad (11)$$

$$R_{Gy} \approx q \delta g r \sin^{-1} \gamma (\varepsilon_2 - \varepsilon_1) (\varepsilon_1 + 0.52) \operatorname{ctg} \gamma \quad (12)$$

$$R''_{Gx} = f_0 (R_{Gz} + R_{Gy}) = F''_{Gx} \quad (13)$$

Forces caused by the soil inertia:

$$R'_{Jx} = q \delta v^2 k_y^{-1} \sin \gamma \left\{ (\sin \gamma \cos \varepsilon_1 + \cos^2 \gamma \sin^{-1} \gamma) e^{f_0 \sin \gamma (\varepsilon_1 - \varepsilon_2)} - (\sin \gamma \cos \varepsilon_2 + \cos^2 \gamma \sin^{-1} \gamma) + (\cos \varepsilon_1 - f_0 \sin \varepsilon_1 \sin \gamma)^{-1} e^{f_0 \sin \gamma (\varepsilon_2 - \varepsilon_1)} * \right. \\ \left. * \sin \varepsilon_1 [\sin \varepsilon_1 \sin \gamma + f_0 (\sin^2 \gamma \cos \varepsilon_1 + \cos^2 \gamma)] \right\} \quad (14)$$

$$R_{Jz} = q \delta v^2 k_y^{-1} \sin \gamma \sin \varepsilon_2 e^{f_0 \sin \gamma (\varepsilon_2 - \varepsilon_1)} \quad (15)$$

$$R_{Jy} \approx q \delta v^2 k_y^{-1} \sin \gamma \cos \gamma (1 - \cos \varepsilon_2) \quad (16)$$

$$R_{Jx} = f_0 (R_{Jz} + R_{Jy}) = F''_{Jx} \quad (17)$$

Forces caused by soil adhesion:

$$R'_{Ax} = p_A b r \sin^{-1} \gamma (e^{f_0 \sin \gamma (\varepsilon_2 - \varepsilon_1)} - 1) * \\ * \left\{ \sin \gamma \cos \varepsilon_1 + \cos^2 \gamma \sin^{-1} \gamma + (\cos \varepsilon_1 - f_0 \sin \varepsilon_1 \sin \gamma)^{-1} * \right. \\ \left. * \sin \varepsilon_1 [\sin \varepsilon_1 \sin \gamma + f_0 (\sin^2 \gamma \cos \varepsilon_1 + \cos^2 \gamma)] \right\} \quad (18)$$

$$R_{Az} = 0$$

(19)

$$R_{Ay} \approx 0$$

(20)

$$R''_{Ax} = f_0(p_{Axy} + p_{Axz}S_{xz}) = F''_{Ax}$$

(21)

where: q – the cross section area of the strip to be lifted; δ – the density of soil; k_y – the soil compaction coefficient in front of the operating part; f_0 – the soil friction coefficient against the surface of the operating element; v – the speed of the movement of the plough body; p_A – the specific force of soil adhesion to the operating surface; b – the surface width of the soil strip; ε_1 and ε_2 are correspondingly the initial and the final angles of the lifting (share-mouldboard) surface; γ – the inclination angle of the horizontal generatrix towards the direction of movement (the wall of the furrow); g – acceleration caused by gravity ($g = 9.81$).

The soil friction coefficient and the specific force of soil adhesion are not constant values. Their values decrease with the increase in speed /Vilde et al., 2004/. This is considered in calculations.

The obtained correlations (10) – (18) show how the initial lifting angle ε_1 of the soil strip (the inclination angle of the share) impacts the draft resistance of the share-mouldboard surface, the resistance of the supporting surfaces and of the plough body in totality. The following graphs (Fig. 2-13) show those changes of the draft resistances depending on the initial lifting angle ε_1 at the angle between the horizontal generatrix of the operating surface and the vertical longitudinal plane $\gamma = 40^\circ$ and at the different speed v .

From the graphs above follows that increasing of the share inclination angle ε_1 leads to increasing of partial resistances caused by soil strip gravity, inertia forces and adhesion and, as a result – increasing the draft resistance R'_x of the share mouldboard surface (lifting surface) of the plough body by 6 % to 13 % (Fig. 2 - 5). The increase of the resistance is more marked at high speeds.

The resistance of the supporting surfaces of the plough body depends on the values of the reacting forces. Yet their value is dependent, in many respects, on the manner of unification and perfection of the hydraulically mounted implements of the tractor. The vertical reaction of the plough with modern tractors having power regulation is transferred to the body of the tractor, and it affects the plough resistance to a considerably lesser degree /Vilde et al., 2004/.

Increasing of the share inclination angle leads to decreasing of the vertical reaction (reaction of the lower supporting surface) caused by soil strip gravity R_{Gx} , exerts less influence on it of the forces caused by inertia and adhesion (Fig. 6 - 8) and leads to increasing of the lateral reactions caused by all of these forces (Fig. 9 - 11). In connection with that the change of the share inclination angle exerts insignificant influence on the draft resistance R''_x of the supporting surfaces (Fig. 12).

Figure 12. Summary draft resistance of the plough body supporting surfaces depending on the initial lifting angle ϵ_1 of the soil strip and speed v

Figure 13. Total draft resistance of the plough body depending on the initial lifting angle ϵ_1 of the soil strip and speed v

Changes of the total draft resistance of the plough body depend on the working regime. If the plough is working in a floating regime, than increasing of the share inclination angle increases the draft resistance R_x of the plough bodies by 2 % to 10 % (Fig. 13), but if the plough is working with power regulation means, the changes of the total draft resistance may follow the draft resistance changes of the share-mouldboard surface.

The materials of the calculations carried out using the correlations indicated above present the values and regularity of the changes in the forces acting on the share-mouldboard and the supporting surfaces, the draft resistance of the share-mouldboard and the supporting surfaces, as well as the total resistance of the plough body and its components under working conditions depending on the body parameters and the working speed. Possibilities to reduce the tillage energy requirement have been clarified.

The obtained materials show that by increasing the initial lifting angle ε_1 (inclination angle of share toward furrow bottom) the draft resistance increases. For economical ploughing the initial lifting angle of the soil strip (the angle between share and furrow bottom) must have a minimal value - $24^\circ \dots 30^\circ$. The smallest inclination angle is not desirable because by wear out of the share there is a possibility at the blunt (threadbare) ploughshare to obtain a rear bevel which can hinder the plough body from going into soil. This phenomenon is observed with the Kverneland plough bodies No.8 having a 20° inclination angle of their outer part. For more safety working in the hard loamy soils its optimal value may be approximately 30° ($28^\circ \dots 32^\circ$).

In the period of the last ten years only few institutions and scientists, such as the National Soil Resources Institute of the Cranfield University at Silso, England, with Professor R. J. Godwin as the head, and the Department of the VIM (All-Russian Institute for the Mechanization of Agriculture) with Doctor of Sciences P. N. Burchenko as the head, have taken part in applied investigations on the impact of the plough body design and the working mode upon its draft resistance /Burchenko, 2001; Godwin et al., 2005/. However, these investigations do not deal with the impact of the share inclination angle on the plough body draft resistance.

In the earlier literature there are some data concerning this issue. Thus, in the studies by Soehne the minimum draft resistance is obtained at the cutting angle $12^\circ \dots 14^\circ$ (calculated) and $\sim 18^\circ \dots 22^\circ$ (measured) /Gill, Wanden Berg, 1967/. In the investigations by Kawamura the minimum draft resistance is obtained at the cutting angle $\sim 17^\circ$ /Gill, Wanden Berg, 1967/. The graphs show that the draft resistance increases when the share inclination (cutting) angle increases.

Similar results are obtained by Russian researchers A. N. Zelenin and G. N. Sineokow. In the studies with cutting perimeters, carried out by Zelenin, the minimum draft resistance, depending on the working depth, is found to be at the inclination angle of the share $16^\circ \dots 30^\circ$ /Zelenin, 1968/. When the working depth increases, the optimum value of the share inclination angle increases.

In the studies carried out by A. I. Surguchew the increase in the cutting angle and velocity causes increased draft resistance. The impact of the working velocity on the draft resistance is more considerable at greater values of the share inclination angle /Zelenin, 1968/.

In the studies carried out by M. E. Macepuro and I. V. Manjuta with a two-sided wedge on peat soils it was found out that the minimum draft resistance, depending on the working depth, appears at the inclination angles from 20° (the working depth 32 cm) to 25° (the working depth 51 cm) /Sineokov, Panov, 1977/.

The data provided by the above-mentioned researchers agree with the results obtained in our investigations and confirm our conclusions.

In such a way, the deduced analytical correlations and the developed computer algorithm enable simulation of the soil coercion forces upon the share-mouldboard surface of the plough body, taking into consideration its draft resistance, as well as determination of the optimum parameters at minimum resistance.

The use of bodies having optimal parameters (inclination angle of the share, inclination angles of the horizontal generatrix, increased bodies working width) allows obtaining good ploughing quality. It also reduces draft resistance by 12...20%, raises correspondingly the efficiency, and saves fuel and financial resources for ploughing /Vilde et al., 2004; Rucins, Vilde, 2004/.

Conclusions

1. The deduced analytical correlations and the developed computer algorithm enable simulation of the soil coercion forces upon the operating surfaces of the plough body, determination of its specific draft resistance depending on the body design, the working parameters and soil properties and motivation of the optimal values of parameters.

2. Presentation of the draft resistance of the plough body as the sum of its components – the cutting resistance of the strip, the resistance caused by its weight, the soil inertia forces and adhesion - allows analysis of the forces acting upon the share-mouldboard surface, finding out the character of their changes depending on speed and the parameters of the surface, and assessment of their ratio in the total resistance.

3. The main parameters affecting the ploughing efficiency are: the initial and the final angles of the lifting (share-mouldboard) surface; the inclination angle of the horizontal generatrix towards the direction of the movement and the regularity of its variation; the thickness of the share edge; the radius of the lifting surface and the area of the lifting and supporting surfaces.

4. By increasing the initial lifting angle (inclination angle of share toward furrow bottom) the draft resistance increases by 2...10%. For more safety working in the hard loamy soils its optimal value may be approximately 30° (28°...32°).

5. The use of bodies having optimal parameters allows obtaining a good ploughing quality, reduction of the draft resistance by 12...20% and a corresponding rise in the efficiency, saving fuel and financial resources for ploughing.
